SELECT Subqueries	3
IN Subqueries	4
HAVING Subqueries	5
Multirow Subquery operator ALL.	6
Attribute list Subqueries	7
Correlated Subqueries	8
SQL Query order of execution	9

First let's outline the basic characteristics of a subquery.

- A subquery is a query (SELECT statement) inside a query
- A subquery is normally expressed inside parentheses
- The first query in the SQL statement is known as the outer query
- The query inside the SQL statement is known as the inner query
- The inner query is executed first
- The output of an inner query is used as the input for the outer query
- The entire SQL statement is sometimes referred to as a nested query

A subquery can return one value or multiple values. To be precise, the subquery can return:

- *One single value (one column and one row)*. This subquery is used anywhere a single value is expected, as in the right side of a comparison expression. Obviously, when you assign a value to an attribute, that value is a single value, not a list of values. Therefore, the subquery must return only one value (One column, one row). If the query returns multiple values, the DBMS will generate an error.
- *A list of values (one column and multiple rows)*. This type of subquery is used anywhere a list of values is expected, such as when using the IN clause. This type of subquery is used frequently in combination with the IN operator in a WHERE conditional expression.

- A *virtual table (multicolumn, multirow set of values)*. This type of subquery can be used anywhere a table is expected, such as when using the FROM clause.

It's important to note that a subquery can return no values at all; it is a NULL. In such cases, the output of the outer query may result in an error or a null empty set depending where the subquery is used (in a comparison, an expression, or a table set).

In the following sections, you will learn how to write subqueries within the SELECT statement to retrieve data from the database.

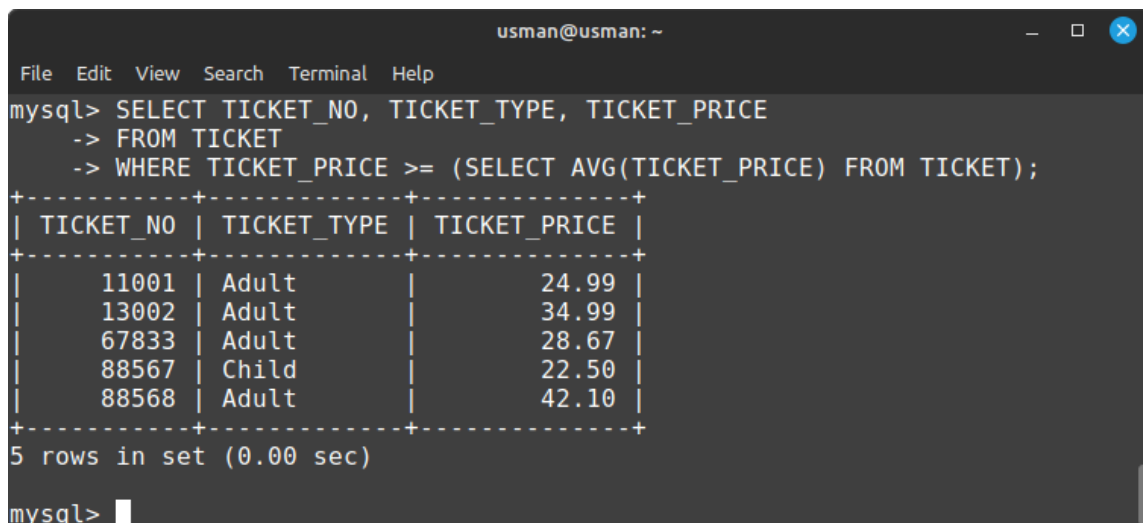

## 1. SELECT Subqueries

The most common type of subquery uses an inner SELECT subquery on the right side of a WHERE comparison expression. For example,

**Task 1** To find the prices of all tickets with a price greater than or equal to the average ticket price, you write the following query:

```
SELECT      TICKET_NO, TICKET_TYPE, TICKET_PRICE
FROM TICKET
WHERE       TICKET_PRICE >= (SELECT AVG(TICKET_PRICE) FROM TICKET);
```

The output of the query is shown in Figure 69.

```
usman@usman: ~
File Edit View Search Terminal Help
mysql> SELECT TICKET_NO, TICKET_TYPE, TICKET_PRICE
-> FROM TICKET
-> WHERE TICKET_PRICE >= (SELECT AVG(TICKET_PRICE) FROM TICKET);
+-----+-----+-----+
| TICKET_NO | TICKET_TYPE | TICKET_PRICE |
+-----+-----+-----+
|      11001 | Adult      |         24.99 |
|      13002 | Adult      |         34.99 |
|      67833 | Adult      |         28.67 |
|      88567 | Child      |         22.50 |
|      88568 | Adult      |         42.10 |
+-----+-----+-----+
5 rows in set (0.00 sec)

mysql> 
```

## Figure 69 Example of SELECT Subquery

Note that this type of query, when used in a  $>$ ,  $<$ ,  $=$ ,  $>=$ , or  $<=$  conditional expression, requires a subquery that returns only one single value (one column, one row). The value generated by the subquery must be of a “comparable” data type; if the attribute to the left of the comparison symbol is a character type, the subquery must return a character string. Also, if the query returns more than a single value, the DBMS will generate an error.

### 2. IN Subqueries

The following query displays all employees who work in a Theme Park that has the word ‘Fairy’ in its name. As there are a number of different Theme Parks that match this criteria you need to compare the PARK\_CODE not to one park code (single value), but to a list of park codes. When you want to compare a single attribute to a list of values, you use the IN operator. When the PARK\_CODE values are not known beforehand but they can be derived using a query, you must use an IN subquery. The following example lists those themeparks who have the tickets of type CHILD.

```
SELECT *  
FROM THEMEPARK  
WHERE PARK_CODE IN (SELECT PARK_CODE FROM TICKET  
WHERE TICKET_TYPE = 'CHILD');
```

The result of that query is shown in Figure 71.

```

usman@usman: ~
File Edit View Search Terminal Help
mysql> SELECT *
-> FROM THEMEPARK
-> WHERE PARK_CODE IN (SELECT PARK_CODE FROM TICKET
-> WHERE TICKET_TYPE = 'CHILD');
+-----+-----+-----+-----+
| PARK_CODE | PARK_NAME | PARK_CITY | PARK_COUNTRY |
+-----+-----+-----+-----+
| SP4533 | AdventurePort | BARCELONA | SP |
| FR1001 | FairyLand | PARIS | FR |
| ZA1342 | GoldTown | JOHANNESBURG | ZA |
| UK3452 | PleasureLand | STOKE | UK |
+-----+-----+-----+-----+
4 rows in set (0.00 sec)

mysql>

```

**Figure 71 Themeparks who have CHILD type tickets.**

**Task 2** Enter and execute the above query and compare your output with that shown in Figure 71.

### 3. HAVING Subqueries

A subquery can also be used with a HAVING clause. Remember that the HAVING clause is used to restrict the output of a GROUP BY query by applying a conditional criteria to the grouped rows. For example, to list all PARK\_CODES where the total quantity of tickets sold is greater than the average quantity sold, you would write the following query:

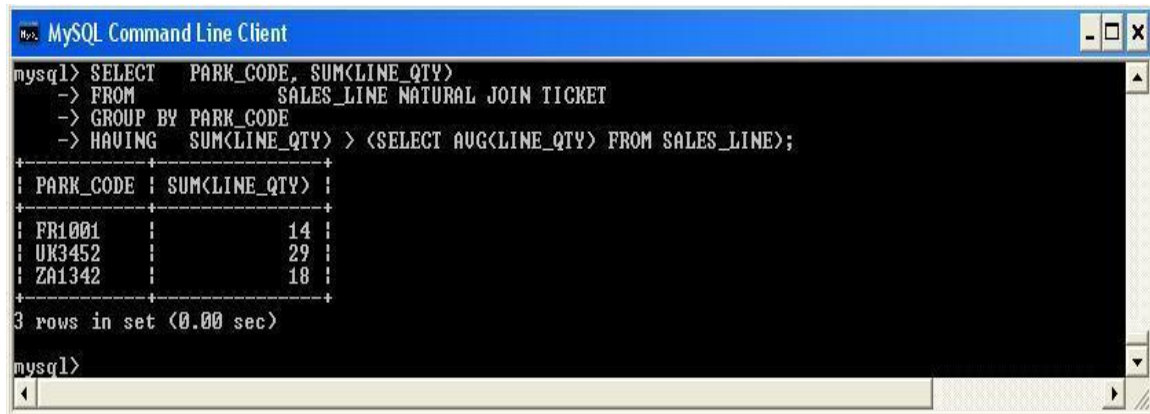

**Task 3**

```

SELECT      PARK_CODE, SUM(LINE_QTY)
FROM        SALES_LINE NATURAL JOIN TICKET
GROUP BY    PARK_CODE
HAVING      SUM(LINE_QTY) > (SELECT AVG(LINE_QTY) FROM SALES_LINE);

```

The result of that query is shown in Figure 72.

```
mysql> SELECT PARK_CODE, SUM(LINE_QTY)
-> FROM SALES_LINE NATURAL JOIN TICKET
-> GROUP BY PARK_CODE
-> HAVING SUM(LINE_QTY) > (SELECT AVG(LINE_QTY) FROM SALES_LINE);
+-----+-----+
| PARK_CODE | SUM(LINE_QTY) |
+-----+-----+
| FR1001    | 14            |
| UK3452    | 29            |
| ZA1342    | 18            |
+-----+-----+
3 rows in set (0.00 sec)

mysql>
```

**Figure 72 PARK\_CODES where tickets are selling above average.**

#### **4. Multirow Subquery operator ALL.**

So far, you have learned that you must use an IN subquery when you need to compare a value to a list of values. But the IN subquery uses an equality operator; that is, it selects only those rows that match (are equal to) at least one of the values in the list. What happens if you need to do an inequality comparison ( $>$  or  $<$ ) of one value to a list of values? For example, to find the ticket\_numbers and corresponding park\_codes of the tickets that are priced higher than the highest-priced 'Child' ticket you could write the following query.

##### **Task 4**

```
SELECT TICKET_NO, PARK_CODE, TICKET_PRICE
FROM TICKET
WHERE TICKET_PRICE > ALL (SELECT TICKET_PRICE FROM TICKET
    WHERE TICKET_TYPE = 'CHILD');
```

The output of that query is shown in Figure 74.

```
mysql> SELECT TICKET_NO, PARK_CODE
-> FROM TICKET
-> WHERE TICKET_PRICE > ALL (SELECT TICKET_PRICE FROM TICKET
-> WHERE TICKET_TYPE = 'CHILD');
+-----+-----+
| TICKET_NO | PARK_CODE |
+-----+-----+
| 11001     | SP4533    |
| 13002     | FR1001    |
| 67833     | ZA1342    |
| 88568     | UK3452    |
+-----+-----+
4 rows in set (0.00 sec)

mysql>
mysql>
```

**Figure 74 Example of ALL.**

This query is a typical example of a nested query. The use of the ALL operator allows you to compare a single value (TICKET\_PRICE) with a list of values returned by the nested query, using a comparison operator other than equals. For a row to appear in the result set, it has to meet the criterion TICKET\_PRICE > ALL of the individual values returned by the nested query.

## 5. Attribute list Subqueries

The SELECT statement uses the attribute list to indicate what columns to project in the resulting set. Those columns can be attributes of base tables or computed attributes or the result of an aggregate function. The attribute list can also include a subquery expression, also known as an inline subquery. A subquery in the attribute list must return one single value; otherwise, an error code is raised. For example, a simple inline query can be used to list the difference between each tickets' price and the average ticket price:

### Task 5

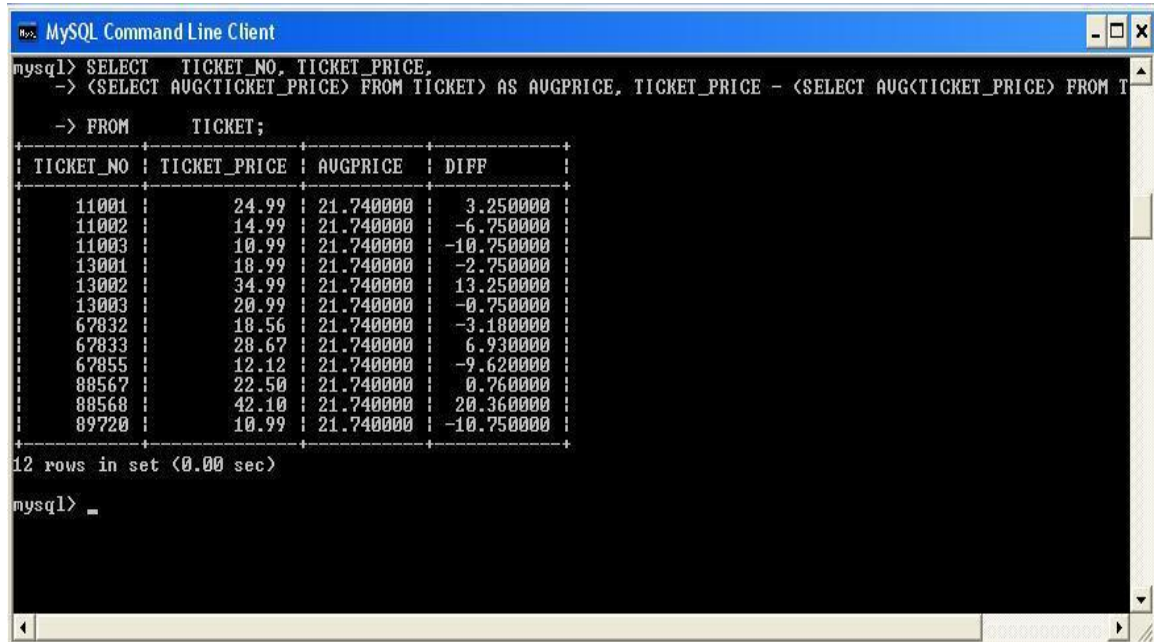

```

SELECT      TICKET_NO, TICKET_PRICE,
            (SELECT AVG(TICKET_PRICE) FROM TICKET) AS AVGPRICE,
            TICKET_PRICE - (SELECT AVG(TICKET_PRICE) FROM TICKET) AS DIFF
FROM TICKET;

```

The output for this query is shown in Figure 75.

```

mysql> SELECT  TICKET_NO, TICKET_PRICE,
-> <SELECT AVG(TICKET_PRICE) FROM TICKET> AS AVGPRICE, TICKET_PRICE - <SELECT AVG(TICKET_PRICE) FROM T
-> FROM      TICKET;

```

TICKET_NO	TICKET_PRICE	AVGPRICE	DIFF
11001	24.99	21.740000	3.250000
11002	14.99	21.740000	-6.750000
11003	10.99	21.740000	-10.750000
13001	18.99	21.740000	-2.750000
13002	34.99	21.740000	13.250000
13003	20.99	21.740000	-0.750000
67832	18.56	21.740000	-3.180000
67833	28.67	21.740000	6.930000
67855	12.12	21.740000	-9.620000
88567	22.50	21.740000	0.760000
88568	42.10	21.740000	20.360000
89720	10.99	21.740000	-10.750000

```

12 rows in set (0.00 sec)

mysql> _

```

**Figure 75 Displaying the difference in ticket prices.**

This inline query output returns one single value (the average ticket's price) and that the value is the same in every row. Note also that the query used the full expression instead of the column aliases when computing the difference. In fact, if you try to use the alias in the difference expression, you will get an error message. The column alias cannot be used in computations in the attribute list when the alias is defined in the same attribute list.

## 6. Correlated Subqueries

A correlated subquery is a subquery that executes once for each row in the outer query. The relational DBMS uses the same sequence to produce correlated subquery results:

1. It initiates the outer query.

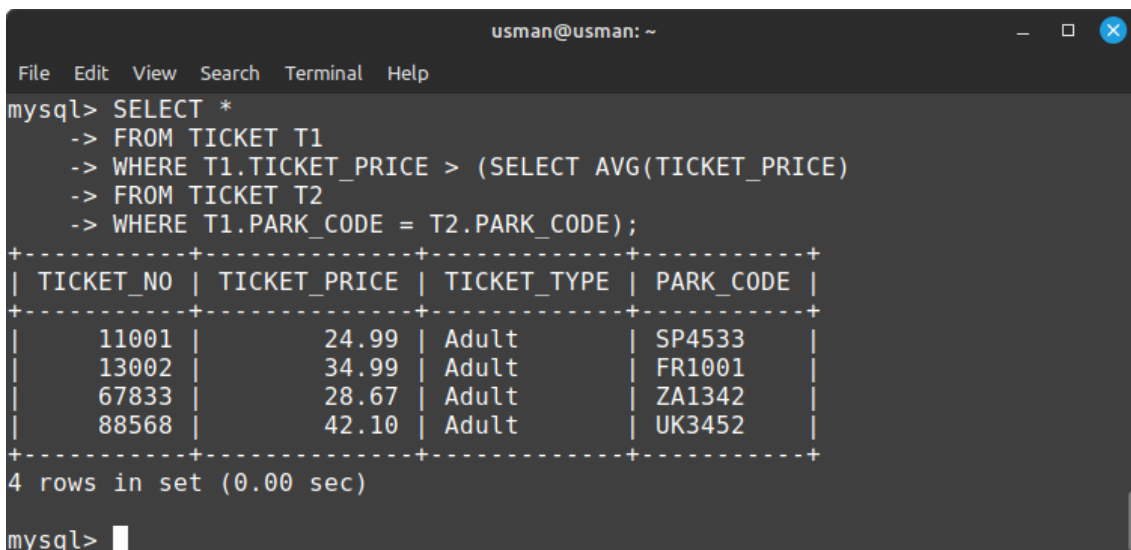

2. For each row of the outer query result set, it executes the inner query by passing the outer row to the inner query.

That process is the opposite of the subqueries you have seen so far. The query is called a *correlated* subquery because the inner query is *related* to the outer query because the inner query references a column of the outer subquery. For example, suppose you want to know all the tickets whose price is greater than the average ticket price for their themepark.

The following correlated query completes the preceding two-step process:

### Task 6

```
SELECT *  
FROM TICKET T1  
WHERE T1.TICKET_PRICE > (SELECT AVG(TICKET_PRICE)  
FROM TICKET T2  
WHERE T1.PARK_CODE = T2.PARK_CODE);
```

The screenshot shows a terminal window with a MySQL prompt. The user has entered a query that selects all columns from the TICKET table (T1) where the ticket price is greater than the average ticket price for the same park code. The results are displayed in a table with 4 rows. The terminal window title is 'usman@usman: ~' and it has a menu bar with 'File', 'Edit', 'View', 'Search', 'Terminal', and 'Help'.

```
mysql> SELECT *  
-> FROM TICKET T1  
-> WHERE T1.TICKET_PRICE > (SELECT AVG(TICKET_PRICE)  
-> FROM TICKET T2  
-> WHERE T1.PARK_CODE = T2.PARK_CODE);  
+-----+-----+-----+-----+  
| TICKET_NO | TICKET_PRICE | TICKET_TYPE | PARK_CODE |  
+-----+-----+-----+-----+  
| 11001 | 24.99 | Adult | SP4533 |  
| 13002 | 34.99 | Adult | FR1001 |  
| 67833 | 28.67 | Adult | ZA1342 |  
| 88568 | 42.10 | Adult | UK3452 |  
+-----+-----+-----+-----+  
4 rows in set (0.00 sec)  
mysql>
```

**Figure 76 Example of a correlated subquery**

As you examine the output shown in figure 76, note that the SALES\_LINE table is used more than once; so you must use table aliases.

ORDER	CLAUSE	FUNCTION
1	from	Choose and join tables to get base data.
2	where	Filters the base data.
3	group by	Aggregates the base data.
4	having	Filters the aggregated data.
5	select	Returns the final data.
6	order by	Sorts the final data.
7	limit	Limits the returned data to a row count.

## 7. SQL Query order of execution

The SQL order of execution defines the order in which the clauses of a query are evaluated. Some of the most common query challenges people run into could be easily avoided with a clearer understanding of the SQL order of execution, sometimes called the SQL order of operations. Understanding SQL query order can help you diagnose why a query won't run, and even more frequently will help you optimize your queries to run faster.

This order is:

### 1. FROM and JOINS

The FROM clause, and subsequent JOINS are first executed to determine the total working set of data that is being queried. This includes subqueries in this clause, and can cause temporary tables to be created under the hood containing all the columns and rows of the tables being joined.

### 2. WHERE

Once we have the total working set of data, the first-pass WHERE constraints are applied to the individual rows, and rows that do not satisfy the constraint are discarded. Each of the constraints can only access columns directly from the tables requested in the FROM clause. Aliases in the SELECT part of the query are not accessible in most databases since they may include expressions dependent on parts of the query that have not yet executed.

### 3. GROUP BY

The remaining rows after the WHERE constraints are applied are then grouped based on common values in the column specified in the GROUP BY clause. As a result of the grouping,

there will only be as many rows as there are unique values in that column. Implicitly, this means that you should only need to use this when you have aggregate functions in your query.

#### **4. HAVING**

If the query has a GROUP BY clause, then the constraints in the HAVING clause are then applied to the grouped rows, discard the grouped rows that don't satisfy the constraint. Like the WHERE clause, aliases are also not accessible from this step in most databases.

#### **5. SELECT**

Any expressions in the SELECT part of the query are finally computed.

#### **6. ORDER BY**

If an order is specified by the ORDER BY clause, the rows are then sorted by the specified data in either ascending or descending order. Since all the expressions in the SELECT part of the query have been computed, you can reference aliases in this clause.

#### **7. LIMIT / OFFSET**

Finally, the rows that fall outside the range specified by the LIMIT and OFFSET are discarded, leaving the final set of rows to be returned from the query.
